# background

- CV&NLP: contrastive SSL has experienced emergence, generative SSL has been gaining steadily significance.
- graph learning: constractive SSL has been the dominant approach, especially for two tasks--node and graph classification.
  - complicated training strategy
  - need negativa samples
  - rely on high qulity data augmentation

self-supervised GAE avoid the issues in constructive learning as its learning strategy is to directly reconstruct the input graph data.

But no GAEs succeed to achieve a comprehensive outperformance over contrastive SSL methods, especially on node and graph classifications

Methods of Adversarial Attack on Graph Structured Data

RL-S2V RANDOM SAMPLING GRADIENT BASED WHITE BOX ATTACK GENETIC **four challenges** that none of the previous GAE collectively deals with:

- the structure information may be over-emphasized
- feature reconstruction without corruption may not be robust
- the mean square error (MSE) can be sensitive and unstable
- the decoder architectures(usually MLP) are of little expressiveness

# a single long-range residual connection

- like ordinary residual connections, it improves the training process by alleviating the vanishing gradient problem
- long-range residual connection can alleviate the over-smoothing problem in the message passing process.

# Dynamic Message Passing Network (dyMPN)

- two hyperparameters: number of iterations/layers L and number of hops  $K_l$ , l = 1, 2, ..., L within each iteration
- dynamic: choose  $K_l$  from some random distribution for layer l. Two choices: random distribution U(a,b) and truncated normal distribution  $\phi(\mu,\sigma,a,b)$

$$m_{\nu}^{l,k} = \mathsf{AGGREGATE}^{l}(\{(h_{\nu}^{l,k-1}, h_{\mu}^{l,k-1}, e_{\mu\nu}) \mid u \in \mathcal{N}_{\nu}\}), \quad (1)$$

$$h_{\nu}^{l,k} = \sigma(W^l m_{\nu}^{l,k} + b^l), \tag{2}$$

individual pre-encoding modules present problems

- dense vectors encoded by GNN have a limited capacity to carry structure information
- training the additional module is difficult due to the increased layers
- additional modules increase parameters and training costs
   GIMLET not only directly unifies the standard language model for graph and text without introducing additional graph encoder module, but also remains the decoupled graph encoding for better generalization.

GNN+LLM-bas Models

Methods of Adversarial Attack on Graph Structured Data

RANDOM SAMPLING GRADIENT BASED WHITE BOX ATTACK GENETIC

$$\max_{\tilde{G}} \qquad \mathbb{I}(f(\tilde{G},c) \neq y)$$

$$s.t. \qquad \tilde{G} = g(f,(G,c,y))$$

$$\mathcal{I}(G,\tilde{G},c) = 1.$$

the graph adversarial attacker  $g(\cdot,\cdot):\mathcal{G}\times\mathcal{D}\mapsto\mathcal{G}$   $\mathcal{I}(\cdot,\cdot,\cdot):\mathcal{G}\times\mathcal{G}\times V\mapsto\{0,1\}$  is an equivalency indicator that tells whether two graphs G and  $\tilde{G}$  are equivalent under the classification semantics

 $\mathbb{I}(\cdot) \in \{0,1\}$  is an indicator function

Methods of Adversarial Attack on Graph Structured Data

Small modifications: ask the attacker to make as few modifications as possible within a neighborhood graph

$$\mathcal{I}(G, \tilde{G}, c) = \mathbb{I}(|(E - \tilde{E}) \cup (\tilde{E} - E)| < m)$$

$$\cdot \mathbb{I}(\tilde{E} \subseteq \mathcal{N}(G, b))). \tag{3}$$

In the above equation, m is the maximum number of edges that allowed to modify, and

 $\mathcal{N}(G, b) = \{(u, v) : u, v \in V, d^{(G)}(u, v) \le b\}$  defines the b-hop neighborhood graph, where  $d^{(G)}(u,v) \in \{1,2,\ldots\}$  is the distance between two nodes in graph G.

# **GradArgmax**

$$\hat{G}_{t+1} = \begin{cases} (\hat{V}_t, \hat{E}_t \setminus (u_t, v_t)) : \frac{\partial \mathcal{L}}{\partial \alpha_{u_t, v_t}} < 0 \\ (\hat{V}_t, \hat{E}_t \cup \{(u_t, v_t)\}) : \frac{\partial \mathcal{L}}{\partial \alpha_{u_t, v_t}} > 0 \end{cases}$$

the gradient considers all pairs of nodes in a graph, the computation cost is at least  $O(|V|^2)$  cannot scale to large graphs.
